## Biomarker Descriptions

### MSH6 p.(K1358Dfs\*2) c.4068\_4071dup

*mutS homolog 6*

**Background:** The MSH6 gene encodes the mutS homolog 6 protein<sup>1</sup>. MSH6 is a tumor suppressor gene that heterodimerizes with MSH2 to form the MutSa complex<sup>2</sup>. The MutSa complex functions in the DNA damage recognition of base-base mismatches or insertion/deletion (indels) of 1-2 nucleotides<sup>2</sup>. DNA damage recognition initiates the mismatch repair (MMR) process that repairs mismatch errors which typically occur during DNA replication<sup>2</sup>. Mutations in MSH2 result in the degradation of MSH6<sup>3</sup>. MSH6, along with MLH1, MSH2, and PMS2, form the core components of the MMR pathway<sup>2</sup>. The MMR pathway is critical to the repair of mismatch errors which typically occur during DNA replication<sup>2</sup>. Deficiency in MMR (dMMR) is characterized by mutations and loss of expression in these genes<sup>4</sup>. dMMR is associated with microsatellite instability (MSI), which is defined as a change in the length of a microsatellite in a tumor as compared to normal tissue<sup>5,6,7</sup>. MSI-high (MSI-H) is a hallmark of Lynch Syndrome (LS), also known as hereditary non-polyposis colorectal cancer, which is caused by germline mutations in MMR genes<sup>5,8</sup>. LS is associated with an increased risk of developing colorectal cancer, as well as other cancers, including endometrial and stomach cancer<sup>6,8,9,10</sup>. Specifically, MSH6 mutations are associated with an increased risk of ovarian and pancreatic cancer<sup>11,12,13,14</sup>.

**Alterations and prevalence:** Somatic mutations in MSH6 are observed in 11% of uterine corpus endometrial carcinoma, 4% colorectal adenocarcinoma, and 3% skin cutaneous melanoma<sup>15,16</sup>. Alterations in MSH6 are observed in pediatric cancers<sup>15,16</sup>. Somatic mutations are observed in 9% of hepatobiliary cancer, 2% of T-lymphoblastic leukemia/lymphoma, 1% of B-lymphoblastic leukemia/lymphoma, and less than 1% of glioma (2 in 297 cases) and bone cancer (2 in 327 cases)<sup>15,16</sup>.

**Potential relevance:** Pembrolizumab (2014) is an anti-PD-1 immune checkpoint inhibitor that is approved for patients with dMMR solid tumors that have progressed on prior therapies<sup>17</sup>. Nivolumab (2015), an anti-PD-1 immune checkpoint inhibitor, is approved alone or in combination with the cytotoxic T-lymphocyte antigen 4 (CTLA-4) blocking antibody, ipilimumab (2011), for patients with dMMR colorectal cancer that have progressed on prior treatment<sup>18,19</sup>. MSH6 mutations are consistent with high grade in pediatric diffuse gliomas<sup>20,21</sup>.

### PTEN p.(K125E) c.373A>G

*phosphatase and tensin homolog*

**Background:** The PTEN gene encodes the phosphatase and tensin homolog, a tumor suppressor protein with lipid and protein phosphatase activities<sup>22</sup>. PTEN antagonizes PI3K/AKT signaling by catalyzing the dephosphorylation of phosphatidylinositol (3,4,5)-trisphosphate (PIP3) to PIP2 at the cell membrane, which inhibits the activation of AKT<sup>23,24</sup>. In addition, PTEN has been proposed to influence RAD51 loading at double strand breaks during homologous recombination repair (HRR) and regulate the G2/M checkpoint by influencing CHEK1 localization through AKT inhibition, thereby regulating HRR efficiency<sup>25</sup>. Germline mutations in PTEN are linked to hamartoma tumor syndromes, including Cowden disease, which are defined by uncontrolled cell growth and benign or malignant tumor formation<sup>26</sup>. PTEN germline mutations are also associated with inherited cancer risk in several cancer types<sup>27</sup>.

**Alterations and prevalence:** PTEN is frequently altered in cancer by inactivating loss-of-function mutations and by gene deletion. PTEN mutations are frequently observed in 50%-60% of uterine cancer<sup>15,16</sup>. Nearly half of somatic mutations in PTEN are stop-gain or frame-shift mutations that result in truncation of the protein reading frame. Recurrent missense or stop-gain mutations at codons R130, R173,

## Biomarker Descriptions (continued)

and R233 result in loss of phosphatase activity and inhibition of wild-type PTEN<sup>24,28,29,30,31</sup>. PTEN gene deletion is observed in 15% of prostate cancer, 9% of squamous lung cancer, 9% of glioblastoma, and 1-5% of melanoma, sarcoma, and ovarian cancer<sup>15,16</sup>.

**Potential relevance:** Due to the role of PTEN in HRR, poly(ADP-ribose) polymerase inhibitors (PARPi) are being explored as a potential therapeutic strategy in PTEN deficient tumors<sup>32,33</sup>. In 2022, the FDA granted fast track designation to the small molecule inhibitor, pidnarulex<sup>34</sup>, for BRCA1/2, PALB2, or other homologous recombination deficiency (HRD) mutations in breast and ovarian cancers. In 2023, the FDA approved the kinase inhibitor, capivasertib<sup>35</sup> in combination with fulvestrant for locally advanced or metastatic hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer with one or more PIK3CA/AKT1/PTEN-alterations following progression after endocrine treatment.
